

Merge-Sort Review

- Merge-sort on an input sequence S with n elements consists of three steps:
 - Divide: partition S into two sequences S₁ and S₂ of about n/2 elements each
 - Conquer: recursively sort
 S₁ and S₂
 - Combine: merge S₁ and S₂ into a unique sorted sequence

Algorithm mergeSort(S)

Input sequence *S* with *n* elements

Output sequence *S* sorted according to *C*

if S.size() > 1

 $(S_1, S_2) \leftarrow partition(S, n/2)$

 $mergeSort(S_1)$

 $mergeSort(S_2)$

 $S \leftarrow merge(S_1, S_2)$

Recurrence Equation Analysis

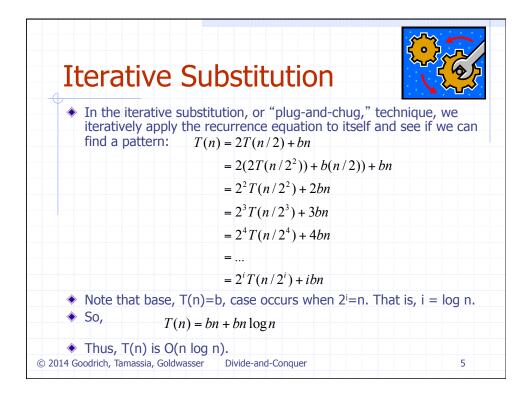

- The conquer step of merge-sort consists of merging two sorted sequences, each with n/2 elements and implemented by means of a doubly linked list, takes at most bn steps, for some constant b.
- Likewise, the basis case (n < 2) will take at b most steps.
- \bullet Therefore, if we let T(n) denote the running time of merge-sort:

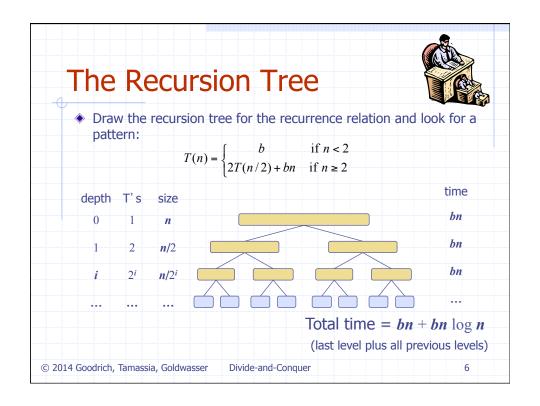

$$T(n) = \begin{cases} b & \text{if } n < 2\\ 2T(n/2) + bn & \text{if } n \ge 2 \end{cases}$$

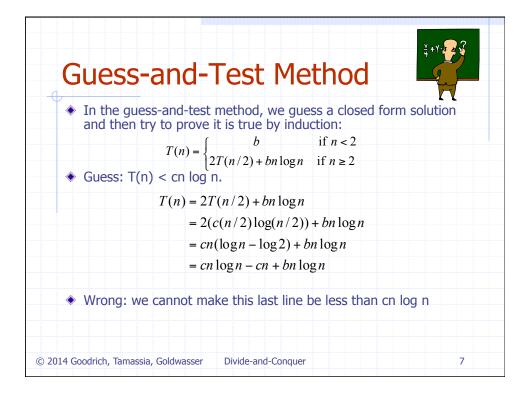

- We can therefore analyze the running time of merge-sort by finding a closed form solution to the above equation.
 - That is, a solution that has T(n) only on the left-hand side.

Divide-and-Conquer

Master Method (Appendix)

Many divide-and-conquer recurrence equations have the form:

$$T(n) = \begin{cases} c & \text{if } n < d \\ aT(n/b) + f(n) & \text{if } n \ge d \end{cases}$$

- The Master Theorem:
 - 1. if f(n) is $O(n^{\log_b a \varepsilon})$, then T(n) is $\Theta(n^{\log_b a})$
 - 2. if f(n) is $\Theta(n^{\log_b a} \log^k n)$, then T(n) is $\Theta(n^{\log_b a} \log^{k+1} n)$
 - 3. if f(n) is $\Omega(n^{\log_b a + \varepsilon})$, then T(n) is $\Theta(f(n))$, provided $af(n/b) \le \delta f(n)$ for some $\delta < 1$.

C

Master Method, Example 1

- The form: $T(n) = \begin{cases} c & \text{if } n < d \\ aT(n/b) + f(n) & \text{if } n \ge d \end{cases}$
- ◆ The Master Theorem:
 - 1. if f(n) is $O(n^{\log_b a \varepsilon})$, then T(n) is $\Theta(n^{\log_b a})$
 - 2. if f(n) is $\Theta(n^{\log_b a} \log^k n)$, then T(n) is $\Theta(n^{\log_b a} \log^{k+1} n)$
 - 3. if f(n) is $\Omega(n^{\log_b a + \varepsilon})$, then T(n) is $\Theta(f(n))$, provided $af(n/b) \le \delta f(n)$ for some $\delta < 1$.
- Example:

$$T(n) = 4T(n/2) + n$$

Solution: $\log_{h} a = 2$, so case 1 says T(n) is O(n²).

Divide-and-Conquer

Master Method, Example 2

- The form: $T(n) = \begin{cases} c & \text{if } n < d \\ aT(n/b) + f(n) & \text{if } n \ge d \end{cases}$
- The Master Theorem:
 - 1. if f(n) is $O(n^{\log_b a \varepsilon})$, then T(n) is $\Theta(n^{\log_b a})$
 - 2. if f(n) is $\Theta(n^{\log_b a} \log^k n)$, then T(n) is $\Theta(n^{\log_b a} \log^{k+1} n)$
 - 3. if f(n) is $\Omega(n^{\log_b a + \varepsilon})$, then T(n) is $\Theta(f(n))$, provided $af(n/b) \le \delta f(n)$ for some $\delta < 1$.
- * Example:

$$T(n) = 2T(n/2) + n \log n$$

Solution: $\log_b a = 1$, so case 2 says T(n) is O(n $\log^2 n$).

Divide-and-Conquer

Iterative "Proof" of the Master Theorem

• Using iterative substitution, let us see if we can find a pattern:

$$T(n) = aT(n/b) + f(n)$$

$$= a(aT(n/b^2)) + f(n/b)) + bn$$

$$= a^{2}T(n/b^{2}) + af(n/b) + f(n)$$

$$= a^{3}T(n/b^{3}) + a^{2}f(n/b^{2}) + af(n/b) + f(n)$$

= ...

$$= a^{\log_b n} T(1) + \sum_{i=0}^{(\log_b n) - 1} a^i f(n/b^i)$$

$$= n^{\log_b a} T(1) + \sum_{i=0}^{(\log_b a) - 1} a^i f(n/b^i)$$

- ♦ We then distinguish the three cases as
 - The first term is dominant
 - Each part of the summation is equally dominant
 - The summation is a geometric series

Integer Multiplication

- Algorithm: Multiply two n-bit integers I and J.
 - Divide step: Split I and J into high-order and low-order bits

$$I = I_h 2^{n/2} + I_l$$

$$J = J_h 2^{n/2} + J_l$$

• We can then define I*J by multiplying the parts and adding:

$$I * J = (I_h 2^{n/2} + I_l) * (J_h 2^{n/2} + J_l)$$

$$= I_h J_h 2^n + I_h J_l 2^{n/2} + I_l J_h 2^{n/2} + I_l J_l$$

- So, T(n) = 4T(n/2) + n, which implies T(n) is $O(n^2)$.
- But that is no better than the algorithm we learned in grade school.

Divide-and-Conquer

An Improved Integer **Multiplication Algorithm**

- Algorithm: Multiply two n-bit integers I and J.
 - Divide step: Split I and J into high-order and low-order bits $I = I_h 2^{n/2} + I_l$

$$J = J_h 2^{n/2} + J_I$$

 $J = J_h 2^{n/2} + J_l$ Observe that there is a different way to multiply parts:

$$I * J = I_h J_h 2^n + [(I_h - I_l)(J_l - J_h) + I_h J_h + I_l J_l] 2^{n/2} + I_l J_l$$

$$= I_h J_h 2^n + [(I_h J_l - I_l J_l - I_h J_h + I_l J_h) + I_h J_h + I_l J_l] 2^{n/2} + I_l J_l$$

$$= I_h J_h 2^n + (I_h J_l + I_l J_h) 2^{n/2} + I_l J_l$$

- So, T(n) = 3T(n/2) + n, which implies T(n) is $O(n^{\log_2 3})$, by the Master Theorem.
- Thus, T(n) is O(n^{1.585}).
